## INTRODUCTION

### Background

- MASLD and its progressive form MASH are among the most common liver disorders worldwide
- MASH is associated with long-term clinical consequences (e.g., liver cirrhosis, decompensation and/or failure, HCC) which may lead to death
- Clinical trials in this population require long follow-up times and large sample sizes to observe sufficient clinical events for statistical comparison
  - Surrogate endpoints (short-term markers that reliably predict clinical outcomes) are commonly used to accelerate drug development and treatment access
- Surrogate endpoints in MASH, such as histologic fibrosis stage and NASH resolution, have been accepted by the FDA<sup>1</sup> and EMA<sup>2</sup> to provide conditional approvals for medications targeted to treat this condition

### Rationale

- Synthesis of the association between histologic fibrosis stage and long-term clinical consequences will inform the appropriateness of surrogate endpoints in MASH

## OBJECTIVES

- Review the existing literature on surrogate endpoints (histologic fibrosis stage) used for MASH
- Examine the relationship between fibrosis stage and clinical outcomes such as mortality and/or liver-related events in patients with MASH

## METHODS

### Search strategy

- Search period:** 2014 to November 13, 2024
- Data sources:** MEDLINE, Embase, clinical trial registries (clinicaltrials.gov, WHO-ICTRP, EU platform), manual search of the reference lists of previous reviews

### Study selection

**TABLE 1. PECOS criteria for identifying relevant studies**

	Inclusion criteria		
Population	Adults with a diagnosis of MASH		
Exposure	Fibrosis stage based on histological assessment		
Comparators	<ul style="list-style-type: none"> <li>F2-3 vs F4</li> <li>Other comparators in which F2 and/or F3 are compared to F4</li> </ul>		
Outcomes	<b>Primary</b> <ul style="list-style-type: none"> <li>Liver transplant</li> <li>Hepatic decompensation on events</li> <li>Progression to cirrhosis</li> <li>ESLD</li> <li>HCC</li> <li>Composite outcomes of the above liver-related events</li> <li>Mortality</li> </ul>	<b>Secondary</b> <ul style="list-style-type: none"> <li>HRQoL</li> </ul>	<b>Exploratory</b> <ul style="list-style-type: none"> <li>CV-related events</li> <li>CV-related mortality</li> <li>MACE</li> <li>Other HRQoL outcomes</li> </ul>
Study design	<ul style="list-style-type: none"> <li>Clinical trials</li> <li>Observational studies</li> <li>Correlational or prognostic studies</li> </ul>		

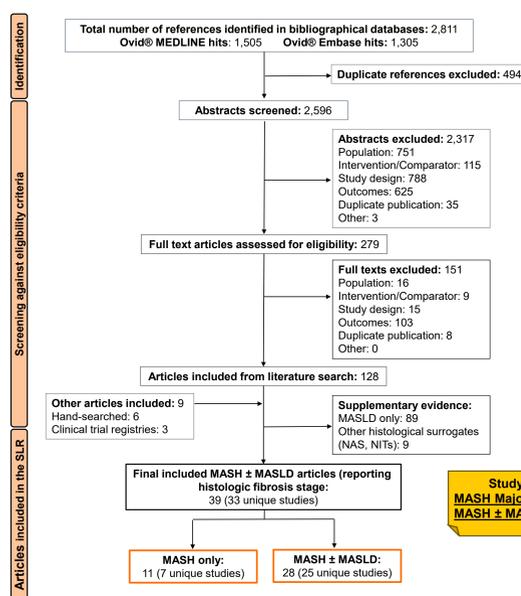

### Evidence synthesis

- If  $\geq 3$  studies were available for an endpoint, meta-analysis conducted
- If  $n < 5$  studies estimating an endpoint, only fixed-effect (FE) model was used
- If  $\geq 5$  studies estimating an endpoint, both random-effects (RE) models (HKSJ method with Paule-Mandel estimator and DL method) and FE model were used
- If  $< 3$  studies were available for endpoint, narrative synthesis conducted only

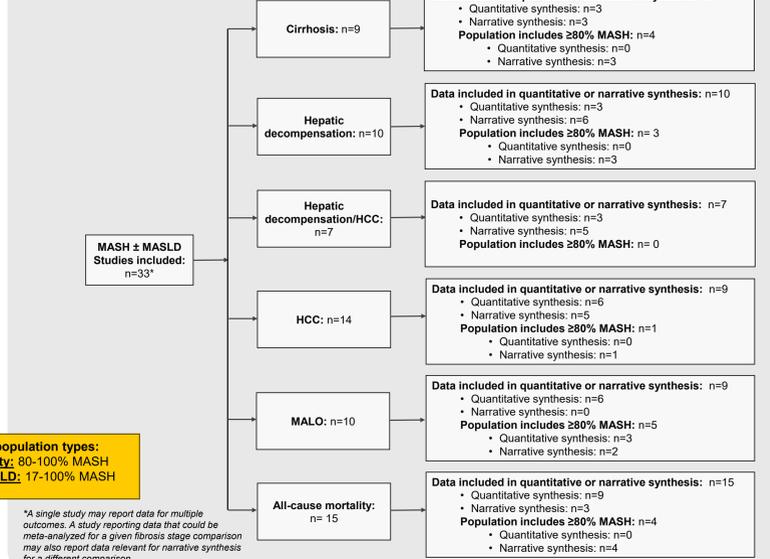

## RESULTS

Thirty-three unique studies examined the relationship between fibrosis stage and clinical outcomes (Figures 1 and 2).

**FIGURE 1. PRISMA diagram.**

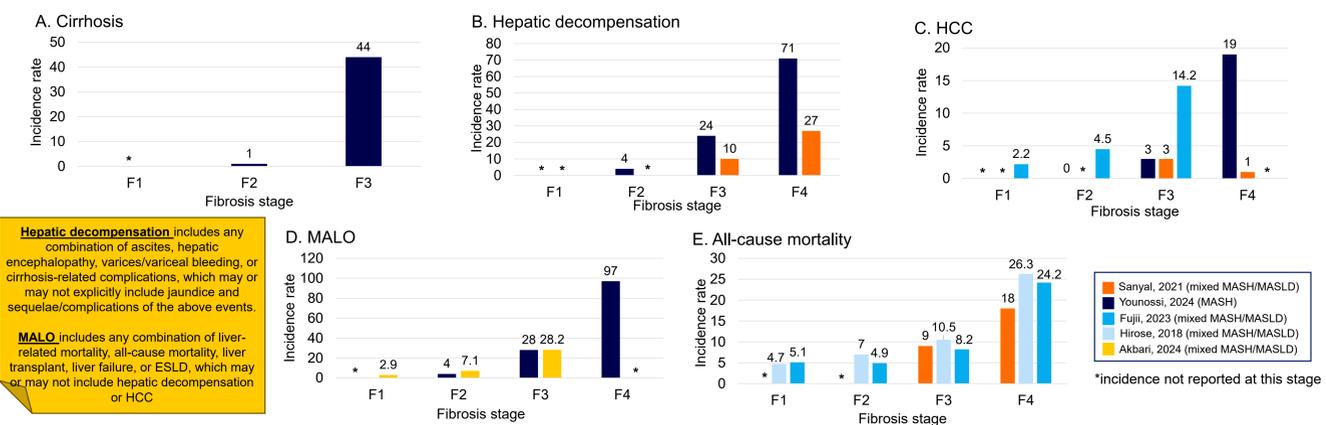

**FIGURE 2. Number of studies contributing to quantitative and narrative syntheses.**

In individual studies, patients at higher F-stages had higher incidence of adverse clinical outcomes compared to those at lower F-stages (Figure 3).

**FIGURE 3. Incidence rate of outcomes per fibrosis stage (per 1000 patient years) in MASH ± MASLD patients**

Patients at higher F-stages had greater risk of adverse clinical outcomes versus those at lower F-stages when pooling data across studies (Table 2).

**TABLE 2. Results of quantitative synthesis in MASH ± MASLD studies**

Outcome	Available comparisons	Adjusted estimates			Unadjusted estimates		
		Final selected model (number of studies)	pooled aHR (95% CI)	I <sup>2</sup> (%)	Final selected model (number of studies)	pooled uHR (95% CI)	I <sup>2</sup> (%)
<b>Cirrhosis, decompensated</b>	F3 vs F2	Fixed effects (n=3)	2.05 (1.45, 2.90)*†	77.6	-	-	-
<b>Hepatic decompensation</b>	F3-4 vs F0-2	Fixed effects (n=3)	10.93 (6.31, 18.92)*	47.8	-	-	-
<b>Hepatic decompensation/ HCC</b>	F3-4 vs F0-2	Fixed effects (n=3)	20.50 (8.25, 50.93)*	59.9	Fixed effects (n=3)	32.37 (13.51, 77.59)*	60.6
<b>HCC</b>	F4 vs F3	Fixed effects (n=3)	1.52 (0.33, 7.10)†	2.7	-	-	-
	F3-4 vs F0-2	PM-HKSJ (n=5)	5.57 (1.87, 16.60)*	17.0	-	-	-
<b>MALO</b>	F4 vs F3	Fixed effects (n=3)	3.27 (1.98, 5.41)*†	45.9	Fixed effects (n=5)	2.43 (1.70, 3.46)*†	64.6
	F4 vs F2	Fixed effects (n=3)	6.31 (3.38, 11.79)*†	72.3	Fixed effects (n=3)	6.62 (3.72, 11.78)*†	71.2
<b>All-cause mortality</b>	F3-4 vs F0-2	PM-HKSJ (n=6)	6.66 (4.04, 10.99)*	34.1	-	-	-
	F4 vs F3	Fixed effects (n=3)	2.13 (1.10, 4.10)*†	0.0	Fixed effects (n=4)	2.30 (1.35, 3.94)*†‡	0.0
	F4 vs F0-2	-	-	-	Fixed effects (n=3)	5.63 (3.15-10.06)*†‡	0.0
	F3-4 vs F0-2	PM-HKSJ (n=9)	3.36 (2.37-4.75)*	0.0	-	-	-

Notes: \*p<0.05, sufficient quantitative data was not available for MASH only studies to estimate unadjusted or adjusted pooled hazard ratios

Data from studies conducted in MASH majority populations are consistent with trends observed in MASH ± MASLD populations (Figure 4).

**FIGURE 4. Number of MASH majority studies showing consistency with MASH ± MASLD results**

## CONCLUSION

- Patients with histologically defined advanced fibrosis and cirrhosis are at increased risk of adverse clinical outcomes compared to patients with earlier stages of fibrosis, including a two- to three-fold increased risk of all-cause mortality, a three- to six-fold increased risk of MALO, and over ten-fold risk of hepatic decompensation.
- These findings support the prognostic relevance of histologic fibrosis stage and its use as a surrogate marker for long-term clinical outcomes in patients with MASH
- Additional longitudinal studies, using either clinical trial or observational designs, are required to support future quantitative analysis in the MASH population
